Extending the Hierarchical Model for Antibody Kinetics

Kwan Ho Lee

UC Davis

2025-05-01

Overview

- Incorporates feedback from Dr. Morrison and Dr.Aiemjoy
- Focus exclusively on (Teunis and Eijkeren 2016) model
- Clarifies model dynamics: growth, clearance, decay
- \bullet Uses updated parameter notation: μ_{y} , μ_{b} , γ , α , ρ
- Assumes block-diagonal covariance structure across biomarkers

Within-Host ODE System (Teunis and Eijkeren 2016)

Two-phase within-host antibody kinetics:

$$\frac{dy}{dt} = \begin{cases} \mu_y y(t), & t \le t_1 \\ -\alpha y(t)^\rho, & t > t_1 \end{cases} \quad \text{with } \frac{db}{dt} = \mu_b b(t) - \gamma y(t) \tag{1}$$

Initial conditions: $y(0) = y_0$, $b(0) = b_0$

Key transition: t_1 is the time when $b(t_1)=0$

 $\mbox{ Derived quantity: } y_1 = y(t_1)$

Closed-Form Solutions

Antibody concentration y(t)

• $t \le t_1$:

$$y(t) = y_0 e^{\mu_y t}$$

• $t > t_1$:

$$y(t) = y_1 \left(1 + (\rho - 1) \alpha y_1^{\rho - 1} (t - t_1) \right)^{-\frac{1}{\rho - 1}}$$

Pathogen load b(t)

• $t \le t_1$:

$$b(t) = b_0 e^{\mu_b t} - \frac{\gamma y_0}{\mu_u - \mu_b} \left(e^{\mu_y t} - e^{\mu_b t} \right)$$

• $t > t_1$:

Time of Peak Response

Peak Time t_1

$$t_1 = \frac{1}{\mu_y - \mu_b} \log \left(1 + \frac{(\mu_y - \mu_b)b_0}{\gamma y_0} \right) \tag{2}$$

Peak Antibody Level y_1

$$y_1 = y_0 e^{\mu_y t_1} \tag{3}$$

Parameter Summary

Table 1: Parameter summary for antibody kinetics model.

Symbol	Description
$ \frac{\mu_y}{\mu_b} \\ \gamma \\ \alpha \\ \rho \\ t_1 \\ y_1 $	Antibody production rate (growth phase) Pathogen replication rate Clearance rate (by antibodies) Antibody decay rate Shape of antibody decay (power-law) Time of peak response Peak antibody concentration

Note: Only the first 6 are typically estimated. y_1 is derived from the ODE solution at t_1 .

Model Comparison: (Teunis and Eijkeren 2016) vs This Presentation

Table 2: Comparison of Teunis (2016) model and this presentation's model assumptions.

Component	(Teunis and Eijkeren 2016)	This Presentation
Pathogen ODE Antibody ODE (pre-t ₁)	$\mu_0 b(t) - c y(t) \\ \mu y(t)$	$\begin{array}{l} \mu_b b(t) - \gamma y(t) \\ \mu_y y(t) \end{array}$
Antibody ODE (post- t_1)	$-\alpha y(t)^r$	$-\alpha y(t)^{ ho}$
Antibody growth type	Pathogen-driven	Self-driven exponential
Antibody rate name	μ	μ_y
t_1 formula	Uses μ_0 , μ , b_0 , c , y_0	Uses μ_b , μ_y , etc.

Full Parameter Model (7 Parameters)

Subject-level parameters:

$$\theta_{ij} \sim \mathcal{N}(\mu_j, \, \Sigma_j), \quad \theta_{ij} = \begin{bmatrix} y_{0,ij} \\ b_{0,ij} \\ \mu_{b,ij} \\ \mu_{y,ij} \\ \gamma_{ij} \\ \alpha_{ij} \\ \rho_{ij} \end{bmatrix}$$

Hyperparameters – Means:

- ullet μ_j : population-level mean vector for biomarker j
- Prior on μ_j :

$$\mu_j \sim \mathcal{N}(\mu_{\mathsf{hyp},j},\,\Omega_{\mathsf{hyp},j})$$

Core Parameters Used for Curve Drawing

In this presentation, we focus on **5 key parameters** required to draw antibody curves:

- y_0 : initial antibody level
- t_1 : time of peak antibody response
- y_1 : peak antibody level
- α : decay rate
- ρ : shape of decay

Note: t_1 and y_1 are $\mbox{derived}\mbox{ from the full model}$ - These 5 are sufficient for prediction and plotting

Classifying Model Parameters ((Teunis and Eijkeren 2016) Structure)

Estimated Parameters (7 total):

- Core model parameters (5): μ_b , μ_u , γ , α , ρ
- Initial conditions (2): y_0 , b_0

Derived Quantity (not estimated):

ullet y_1 : peak antibody level computed as $y(t_1)$

Time of Pathogen Clearance t_1

Definition: t_1 is the time when the pathogen is cleared, i.e., $b(t_1)=0$

Analytic expression:

$$t_1 = \frac{1}{\mu_y - \mu_b} \log \left(1 + \frac{(\mu_y - \mu_b)b_0}{\gamma y_0}\right)$$

Key observations: t_1 depends on μ_b , μ_y , b_0 , y_0 , and $y_1=y(t_1)$ is computed based on this time point

Why It's a Seven-Parameter Model

- Our model estimates 7 parameters:
 - 5 biological parameters: μ_b , μ_y , γ , α , ρ
 - 2 initial conditions: y_0 , b_0
- ullet But we often refer to an 8th quantity: y_1
- So why isn't y_1 a parameter?

Answer: y_1 is a **computed value**, not directly estimated.

Why y_1 Is Not Fit Directly

• y_1 is the antibody level at the time the pathogen is cleared:

$$y_1 = y(t_1)$$
 where $b(t_1) = 0$

- y_1 is not an "input" it is **computed** from:
 - μ_{y} , y_{0} , b_{0} , μ_{b} , γ
 - \bullet via solution of ODEs to find t_1 and compute $y(t_1)$

In other words: y_1 is a **derived output**, not a fit parameter.

How y_1 Is Computed

• y_1 is computed by solving the ODE system:

$$\frac{dy}{dt} = \mu_y y(t), \quad \frac{db}{dt} = \mu_b b(t) - \gamma y(t)$$

• Evaluate y(t) at $t=t_1$ using ODE solution:

$$y_1=y(t_1;\mu_y,y_0,b_0,\mu_b,\gamma)$$

Recap: What We Estimate

Seven model parameters (7-parameter model for full dynamics):

- μ_b , μ_u , γ , α , ρ (biological process)
- y_0 , b_0 (initial state)

Derived quantity:

ullet $y_1=y(t_1)$ — not directly estimated, computed

5-parameter subset for curve visualization:

 $\bullet \ y_0, \ y_1, \ t_1, \ \alpha, \ \rho$

Hierarchical Bayesian Structure

Individual parameters:

$$\theta_{ij} = \begin{bmatrix} y_{0,ij} \\ b_{0,ij} \\ \mu_{b,ij} \\ \mu_{y,ij} \\ \gamma_{ij} \\ \alpha_{ij} \\ \rho_{ij} \end{bmatrix} \sim \mathcal{N}(\mu_j, \, \Sigma_j)$$

Hyperparameters:

- μ_j : population-level means (per biomarker j)
- Σ_i : 7×7 covariance matrix over parameters

Subject-Level Parameters: θ_{ij}

$$\theta_{ij} \sim \mathcal{N}(\mu_j, \, \Sigma_j), \quad \theta_{ij} \in \mathbb{R}^7$$

Where:

$$\theta_{ij} = \begin{bmatrix} y_{0,ij} \\ b_{0,ij} \\ \mu_{b,ij} \\ \mu_{y,ij} \\ \gamma_{ij} \\ \alpha_{ij} \\ \rho_{ij} \end{bmatrix}, \quad \Sigma_j \in \mathbb{R}^{7 \times 7}$$

Each subject i has a unique 7-parameter vector per biomarker j, capturing individual-level variation in antibody dynamics.

Hyperparameters: Priors on Population Means

Population-level means:

$$\boldsymbol{\mu}_j \sim \mathcal{N}(\boldsymbol{\mu}_{\mathrm{hyp},j}, \boldsymbol{\Omega}_{\mathrm{hyp},j})$$

Interpretation:

- ullet μ_j : average parameter vector for biomarker j
- $\mu_{\text{hyp},j}$: prior guess (e.g., vector of zeros)
- \bullet $\Omega_{\mathrm{hyp},j}^{\mathrm{TTS}}$: covariance matrix encoding uncertainty

Example:

$$\mu_{\mathrm{hyp},j} = 0, \quad \Omega_{\mathrm{hyp},j} = 100 \cdot I_7$$

Hyperparameters: Priors on Covariance

Covariance across parameters:

$$\Sigma_j^{-1} \sim \mathcal{W}(\Omega_j, \nu_j)$$

- Σ_i : variability/covariance in subject-level parameters
- Ω_i : prior scale matrix
- \bullet ν_i : degrees of freedom

Example:

$$\Omega_j = 0.1 \cdot I_7, \quad \nu_j = 8$$

Measurement Error and Precision Priors

Observed antibody levels:

$$\log(y_{\mathsf{obs},ij}) \sim \mathcal{N}(\log(y_{\mathsf{pred},ij}), \tau_j^{-1})$$

Precision prior:

$$\tau_j \sim \mathsf{Gamma}(a_j,b_j)$$

- τ_i : shared measurement precision for biomarker j
- Gamma prior allows flexible noise modeling

Matrix Algebra Computation

Let K = 7 (parameters), J biomarkers. Then:

$$\Theta_i = \begin{bmatrix} \theta_{i1} & \theta_{i2} & \cdots & \theta_{iJ} \end{bmatrix} \in \mathbb{R}^{K \times J}$$

Assume:

$$\mathrm{vec}(\Theta_i) \sim \mathcal{N}(\mathrm{vec}(M), \Sigma_K \otimes I_J)$$

Matrix Algebra – Simplified Structure

Setup: $\Theta_i \in \mathbb{R}^{7 \times J}$

Model:

$$\mathrm{vec}(\Theta_i) \sim \mathcal{N}(\mathrm{vec}(M), \Sigma_K \otimes I_J)$$

- Σ_K : 7×7 covariance (same across biomarkers)
- ullet I_J : biomarkers assumed uncorrelated
- Block-diagonal covariance

Understanding $vec(\Theta_i)$

Each $\theta_{ij} \in \mathbb{R}^7$:

$$\theta_{ij} = \begin{bmatrix} y_0 \\ b_0 \\ \mu_0 \\ \mu_1 \\ c \\ \alpha \\ r \end{bmatrix}$$

Flattening:

$$\operatorname{vec}(\Theta_i) \in \mathbb{R}^{7J \times 1}$$

Understanding vec(M)

Let
$$M = [\mu_1 \, \mu_2 \, \cdots \, \mu_J] \in \mathbb{R}^{7 imes J}$$

Example for J=3:

$$M = \begin{bmatrix} \mu_{1,1} & \mu_{1,2} & \mu_{1,3} \\ \mu_{2,1} & \mu_{2,2} & \mu_{2,3} \\ \mu_{3,1} & \mu_{3,2} & \mu_{3,3} \\ \mu_{4,1} & \mu_{4,2} & \mu_{4,3} \\ \mu_{5,1} & \mu_{5,2} & \mu_{5,3} \\ \mu_{6,1} & \mu_{6,2} & \mu_{6,3} \\ \mu_{7,1} & \mu_{7,2} & \mu_{7,3} \end{bmatrix}$$

Covariance Structure: $\Sigma_K \otimes I_J$

$$\mathsf{Cov}(\mathsf{vec}(\Theta_i)) = \Sigma_K \otimes I_J$$

- \bullet Σ_K : parameter covariance matrix
- \bullet I_J : biomarker-wise independence
- Kronecker product yields block-diagonal matrix

Example: Kronecker Product with K=2, J=3

Let:

$$\Sigma_K = \begin{bmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{bmatrix}, \quad I_3 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Then:

$$\Sigma_K \otimes I_3 \in \mathbb{R}^{6 \times 6}$$

Expanded Matrix: $\Sigma_K \otimes I_3$

$$\Sigma_K \otimes I_3 = \begin{bmatrix} \sigma_{11} & 0 & 0 & \sigma_{12} & 0 & 0 \\ 0 & \sigma_{11} & 0 & 0 & \sigma_{12} & 0 \\ 0 & 0 & \sigma_{11} & 0 & 0 & \sigma_{12} \\ \sigma_{21} & 0 & 0 & \sigma_{22} & 0 & 0 \\ 0 & \sigma_{21} & 0 & 0 & \sigma_{22} & 0 \\ 0 & 0 & \sigma_{21} & 0 & 0 & \sigma_{22} \end{bmatrix}$$

Next Steps: Modeling Correlation Across Biomarkers

Current Limitation:

ullet Biomarkers assumed independent: I_J

Planned Extension:

• Use full covariance Σ_J :

$$\mathsf{Cov}(\mathsf{vec}(\Theta_i)) = \Sigma_K \otimes \Sigma_J$$

Extending to Correlated Biomarkers

Assume
$$K=3$$
, $J=3$

Define:

$$\Sigma_K = \begin{bmatrix} \sigma_{11} & \sigma_{12} & \sigma_{13} \\ \sigma_{21} & \sigma_{22} & \sigma_{23} \\ \sigma_{31} & \sigma_{32} & \sigma_{33} \end{bmatrix}, \quad \Sigma_J = \begin{bmatrix} \tau_{11} & \tau_{12} & \tau_{13} \\ \tau_{21} & \tau_{22} & \tau_{23} \\ \tau_{31} & \tau_{32} & \tau_{33} \end{bmatrix}$$

Kronecker Product Structure: $\Sigma_K \otimes \Sigma_J$

$$\Sigma_K \otimes \Sigma_J = \begin{bmatrix} \sigma_{11} \Sigma_J & \sigma_{12} \Sigma_J & \sigma_{13} \Sigma_J \\ \sigma_{21} \Sigma_J & \sigma_{22} \Sigma_J & \sigma_{23} \Sigma_J \\ \sigma_{31} \Sigma_J & \sigma_{32} \Sigma_J & \sigma_{33} \Sigma_J \end{bmatrix}$$

Now biomarkers and parameters can be correlated.

Expanded Form: $\Sigma_K \otimes \Sigma_J$ (3x3)

The 9×9 matrix contains all combinations $\sigma_{ab}\tau_{cd}$

Not block-diagonal — includes cross-biomarker correlation

Practical To-Do List (for Chapter 2)

Model Implementation:

- \bullet Define full Σ_J and prior: $\Sigma_J^{-1} \sim \mathcal{W}(\Psi, \nu)$
- \bullet Implement $\Sigma_K \otimes \Sigma_J$ in JAGS

Simulation + Validation:

- Simulate individuals with correlated biomarkers
- Fit both block-diagonal and full-covariance models
- Compare fit: DIC, WAIC, predictive checks
